1 introduction

- 2 Task Description and Requirements
- 2.1 Description
- 2.2 Requirements

3 Prestudy

Methods:

Visualization:

Generating graphs and diagrams representing the program Easier to get an overview of program structure and execution generation based on code itself, or trace of program execution, former easiest to use for class diagrams, latter for sequence diagrams and other types of runtime representation.

Interactive forwards- and backwards-stepping two forms: re-execution, state-saving re-execution: small memory footprint, slow backward stepping state-save: fast stepping both ways, needs more memory, amount depending on program. Slower in general due to overhead of saving every change of programstate, but can be fast enough to not be noticed. Will again depend on the program.

Queries:

fast way to check object-relations and -properties Ask the debugger to evaluate a statement concerning the state of the debugged program. E.g. checking constraints or invariants, making sure relations are correct, why did something happen, etc.

Tools:

GNU debugger (GDB) tracing, reverse debugging, general debug-stuff multiplatform, multi-language remote debugging CLI-only, needs separate front-end

Jinsight
made by IBM
two components: profiler and visualizer
only for z/OS or Linux on system z
builds a trace when application is running
client connects to profiler and visualizes the trace
modified JVM?
120 minute trace limit
very powerful

Javavis

relies on the Java Debug Interface (JDI), and the Vivaldi Kernel (a visualization library) shows dynamic behavior of running program object diagrams+sequence diagram, UML

smooth transitions not a debugger

code canvas (visual studio) unites all project-files on a infinite zoomable surface both content and info layers of visualization - files/folders, diagrams, tests, editors, traces ++ several layers visible at the same time search

trace viewer plugin (g-Eclipse) g-eclipse=grid, archived project visualize and analyze communication of message-passing programs standalone/platform independent designed for massive parallelism debugging event markers

Whyline Interrogative debugger why did, why did not works on recorded executions

TOD: Trace-Oriented Debugger omniscient debugger queries dynamic visualizations - high-level, graph of event density

Jive

combines all fields

contour diagram - Enhanced object diagram, showing objects and their environments: fields, values, relations, inheritance, etc.

sequence diagram - generated during execution, supports zooming and folding to cope with, and hide irrelevant information, but can still become quite large. stepping - state-saving enables fast backward stepping, and the current state is reflected in the diagrams.

queries - enabled by state-saving can be used for debugging

4 Conclusion

References
